The resistance of plasticised PVC, Nylon, Polyester Elastomer Lining, low density Polyethylene & Polyurethane to a wide range of chemicals is listed in the following table.

The symbols used to denote performance are as follows:-

✓ **Satisfactory**

? **Some attack or absorption:** the material may be considered for use when alternative materials are unsatisfactory and where limited life is acceptable. When PVC is to be used with such chemicals fullscale trials under realistic conditions are particularly necessary.

x **Unsatisfactory:** so rated because of decomposition, solution, swelling, loss of ductility etc. of the samples tested.

In order to give guidance, the resistance of PVC to some chemicals has been predicted from its resistance to other chemicals which have a similar composition. Such predictions are shown using an asterisk (\*) with the symbols listed above.

It may be safely assumed that chemical resistance decreases with both increasing temperature and with increasing concentration of reagent, and that the reverse is also true.

No valid assumptions can be made, however, if the temperature and concentration move in compensating directions. The rating 'some attack or absorption' (symbol - ?) should not be assumed to apply at conditions different from those shown.

**Chemical resistance of polyurethane hoses and composite hoses sleeved with polyurethane.**

The polyurethane is not recommended for continuous use in contact with water above 40°C (or solutions containing water above 40°C) because of its hydrolising effect. Hydrolysis can also occur with long exposure to:

- high humidity at elevated temperatures,
- acid and alkali solutions,
- aerated water,
- fungi and bacteria.

Some substances having a satisfactory rating may give swelling but this is usually minimal. The assumption should not be made that this indicates deterioration of the polyurethane.
